“What’s Really Distributed in Distributed Autonomy?”

August 7, 2019 | 1:00 PM ET

Prof. Azad Madni, Ph.D., SERC Principal Investigator

University of Southern California

azad.madni@usc.edu

- ❑ Today’s session will be recorded.
- ❑ An archive of today’s talk will be available at: www.sercuarc.org/serc-talks/ as well as on the [SERC YouTube channel](#).
- ❑ Use the Q&A box to queue questions, reserving the chat box for comments, and questions will be answered during the last 5-10 minutes of the session.
- ❑ If you are connected via the dial-in information only, please email questions or comments to SERCTalks@stevens.edu.
- ❑ Any issues? Use the chat feature for any technical difficulties or other comments, or email SERCTalks@stevens.edu.

Outline

- 21st Century DoD Systems
- Distributed Autonomy Research
 - Engineered Resilience
 - Cyber-Physical-Human Systems
- Multi-Model-based Approach
- Illustrative Example
- Prototype System
- Findings To-Date
- Takeaways

21st Century DoD Systems

- High complexity (hyper-connectivity, interdependencies)
- Need to operate safely for extended periods in dynamic, uncertain environments subject to disruptions
- Long-lived (> 20 years)
- Likely to be extended / adapted over lifetime
- Stringent physical and cyber security requirements
- Adaptive and distributed autonomy

Need new modeling methods and tools

Distributed Autonomy

The extent to which a team of agents can **sense** its environment, **plan** collaboratively based on a priori and sensed knowledge about the environment, and **act** in concert upon that environment to accomplish task-specific goals assigned by an external agent (e.g., human), or created by the agent team without external intervention

Distributed Autonomy Research

■ Formal and Probabilistic Modeling in Resilient System Design (sponsor: SERC)

- **Formal** – provable correctness
- **Probabilistic** – adapt to uncertainty
- **Challenges** - partial observability, unexpected / unknown disruptions; noisy sensors

■ Adaptive Cyber-Physical-Human Systems (sponsor: SERC)

- **Adaptive** – respond to contingencies; learn from evidence
- **Challenges** - incomplete initial system model; human variability; insertion of human (model) in control loop; dynamic context; changing autonomy

Engineered Resilience is A Messy Problem...Why?

- **Requirements:** can be imprecise
- **Actions:** can be unclear
- **Environment:** can be unknown or partially known
- **System states:** can be ambiguous

**These characteristics are incompatible
with traditional modeling methods**

Cyber-Physical-Human Systems

(Madni et al., 2018)

- A class of safety-critical socio-technical systems in which interactions between *physical system* and *cyber elements* that control its operation are influenced by *human agent(s)*
- System objectives achieved through interactions between:
 - **Physical system** (or process) to be controlled
 - **Cyber elements** (i.e., communication links and software)
 - **Human agents** who monitor and influence cyber-physical system operation
- **Distinguishing Feature:** Human (agents) intervene to:
 - redirect cyber-physical elements or supply needed information
 -not just to exercise manual over-ride or assume full control

Exemplar CPHS

Safety-critical systems - range from a small device to SoS

- Self-Driving Vehicles
- Smart Buildings
- Smart Manufacturing
- Medical Devices
- Unmanned Aerial Vehicles

Adaptive CPHS

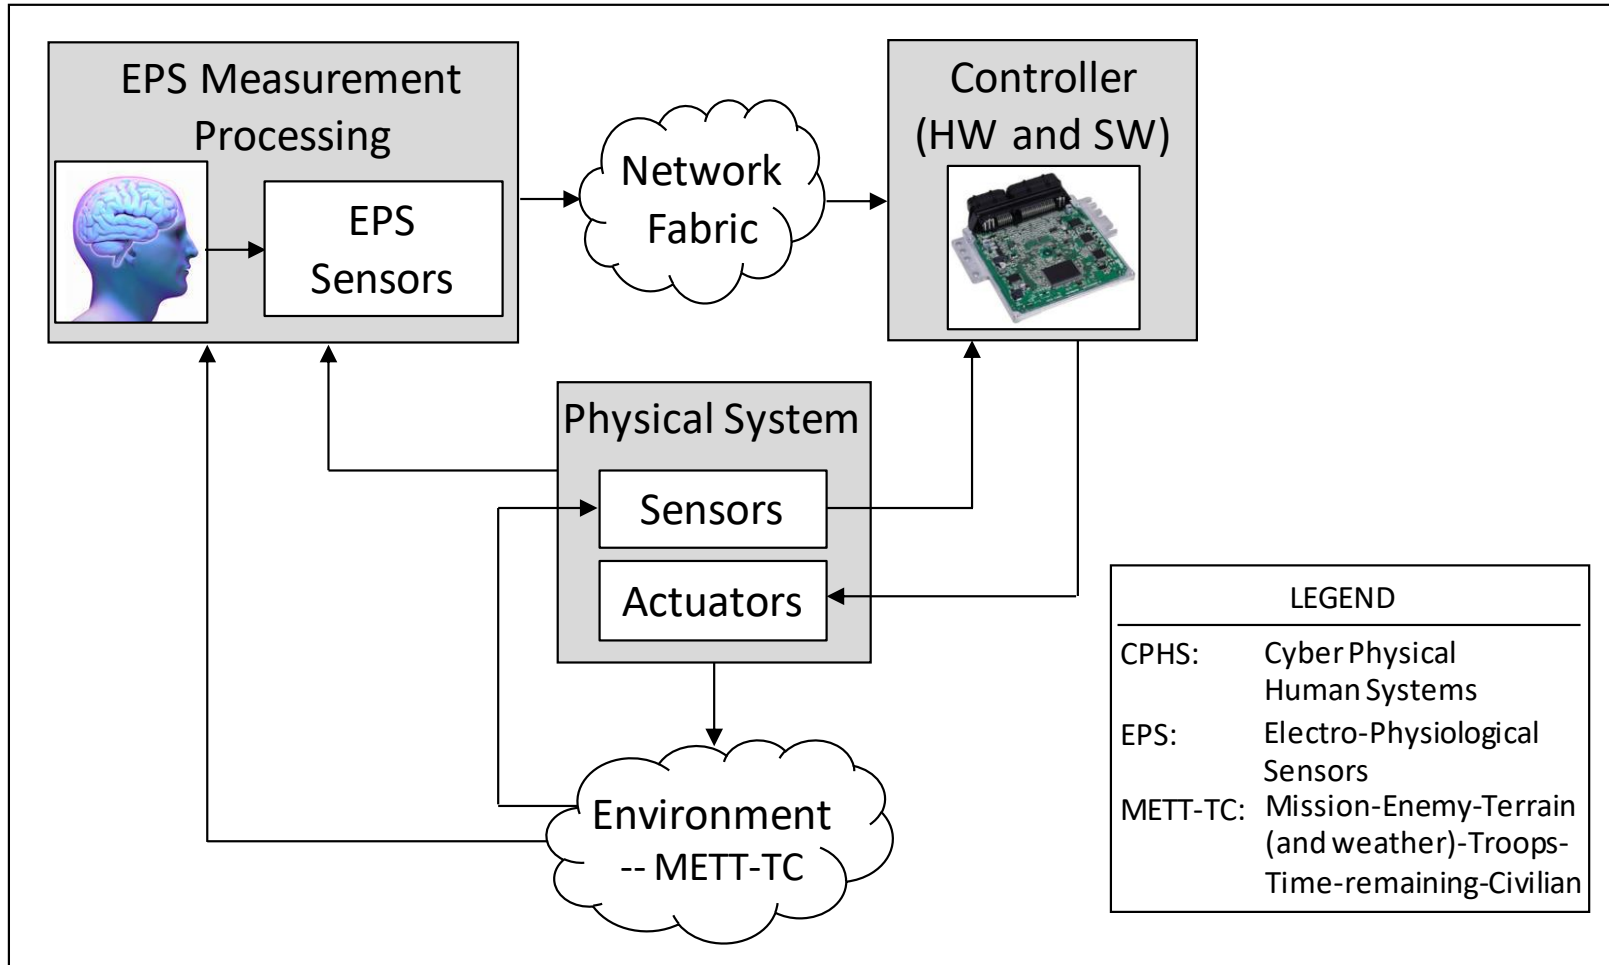

- Respond to disruptions and changes in context
- Leverage unique human capabilities
- Exploit human versatility
- Circumvent human limitations
- Exploit cyber-physical system capabilities
- Learn from experience (observations, outcomes) using ML

What Can Be Distributed in Adaptive CPHS?

- Sensing
 - distributed among fixed sensors, humans, mobile robots
- Planning
 - distributed between humans and cognitive agents
- Decision Making
 - distributed between humans and cognitive agents
- Control
 - distributed between human and actuation agents
- Learning
 - distributed between machine learning agents

Adaptive CPHS System Concept

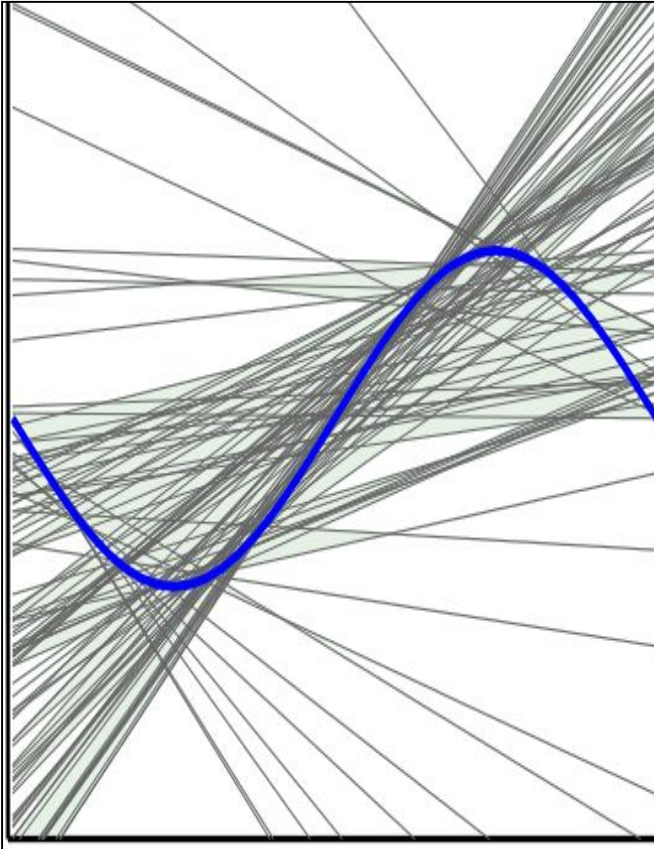

Deficiencies in Existing Modeling Methods and Tools

- **Methods:** Ill-suited for modeling tightly-coupled, sociotechnical learning systems
 - lack semantics of time
 - lack ability to improve with use
 - lack semantics for adequately representing human behavior
 - lack flexibility to represent human behavior with variable fidelity
 - lack learning ability (offline, in-situ)
- **Tools:** reflect methodological deficiencies
 - address cyber, physical, and human elements in isolation
 - focus primarily on subsystems, not their interactions, dependencies and synchronization constraints
 - “build-time” approaches -- no provision for “run-time” learning
 - impoverished human behavior representation

Systems Modeling

- Many different approaches – choice depends on characteristics of the system and the environment
- Different aspects of system behavior represented by different models
 - need to harmonize them
- Most serious problem results from the gap between requirements and models that need to reflect requirements
 - contributes to poor flow down of system requirements to software requirements

System Modeling Requirements

- Verifiability (provable correctness)
- Flexibility (adapt to changing conditions)
- Bidirectional reasoning support (resilient response)
- Scalability and extensibility (no. of agents, interconnections)
- Utility with partial information (not “data hungry”)
- Learn from new observations (evidence-based learning)

Multi-Model Based Approach

■ Modeling Constructs

- formal modeling
- probabilistic modeling
- optimization (e.g., fitness functions)
- machine learning

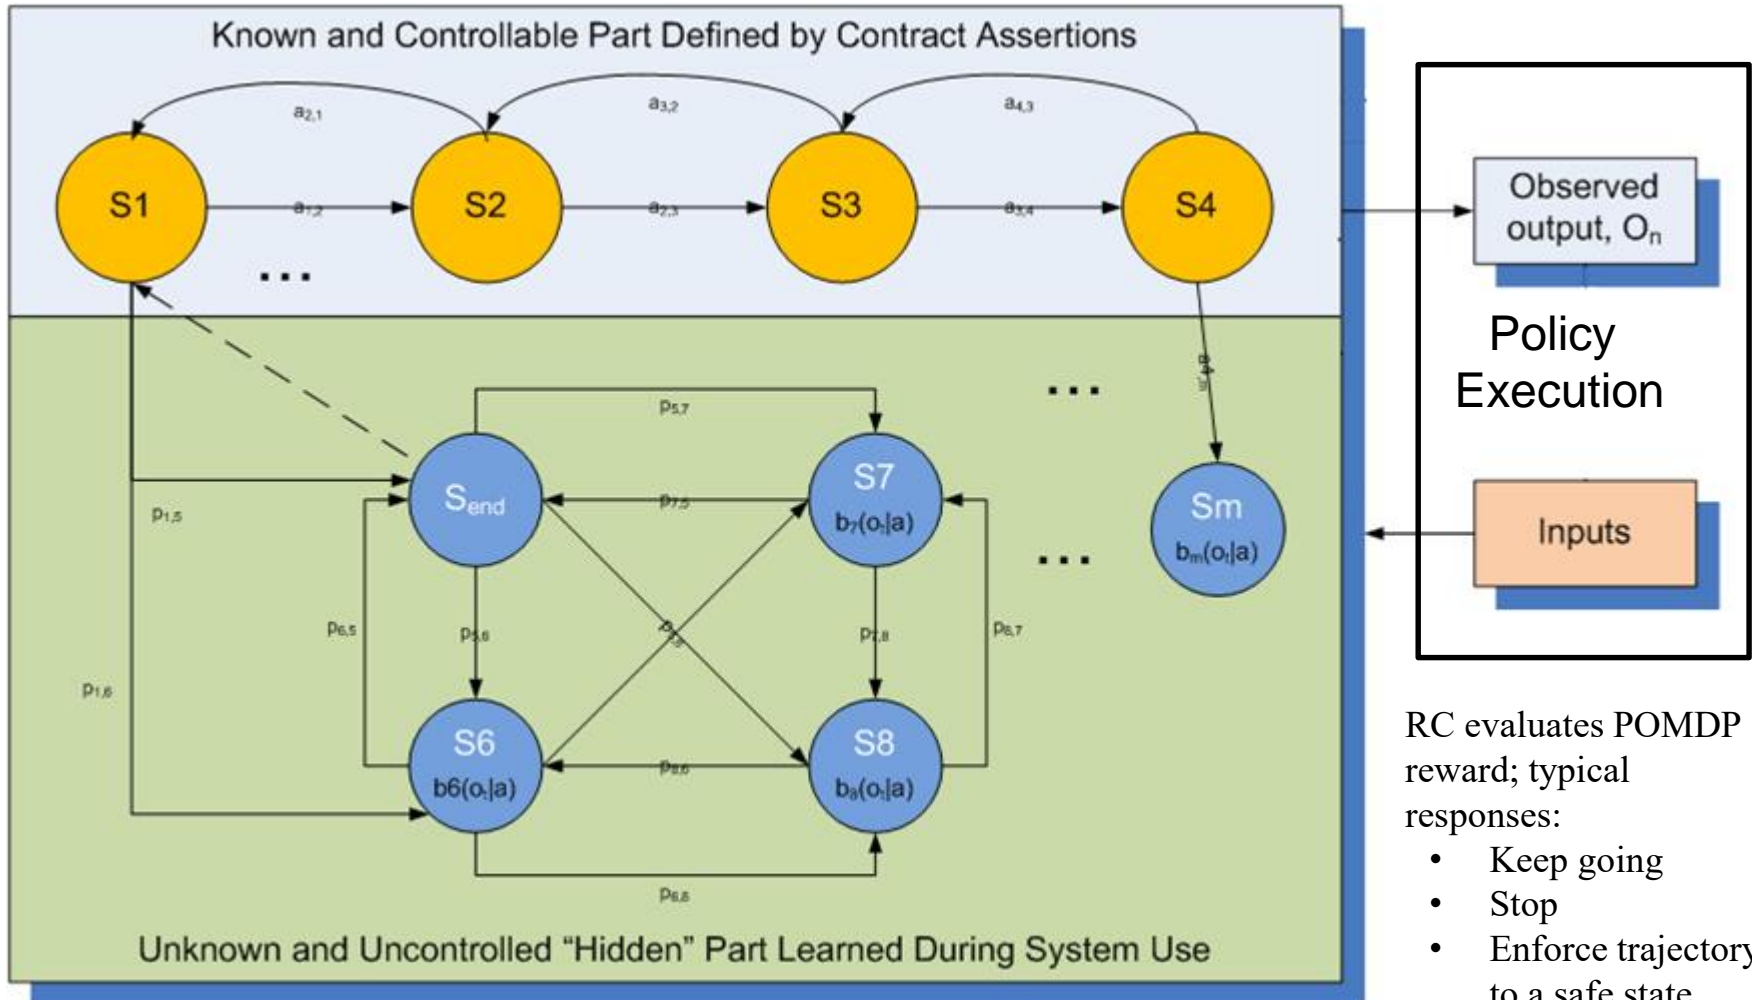

■ Model Uses

- planning and decision making
- simulated/physical system control
- human behavior modeling
- incremental learning of system and environment states

■ Model Visualization

- context-aware dashboard with visual cueing
- multi-perspective, multi-level

Resilience Contract (RC)

- RC evaluates POMDP reward; typical responses:
- Keep going
 - Stop
 - Enforce trajectory to a safe state
 - Notify support team

Illustrative Example: Perimeter Security of C-130 Aircraft

Prototype Scope: Perimeter Security of C-130 Aircraft

- Multiple QCs with downward-facing video cameras
- Building-mounted video cameras and LWIRs
- QCs hold position and altitude that maximizes a collective fitness function (FF)
 - FF reflects perimeter coverage
 - QCs can change position and altitude to maximize FF
- **Contingencies:** low battery causing QC to land; loss of QC
- **Resilience responses:** reposition remaining QCs to restore coverage; launch backup QC if repositioning does not work

QC position relative to a reconnaissance target (red star) and FOV (blue)

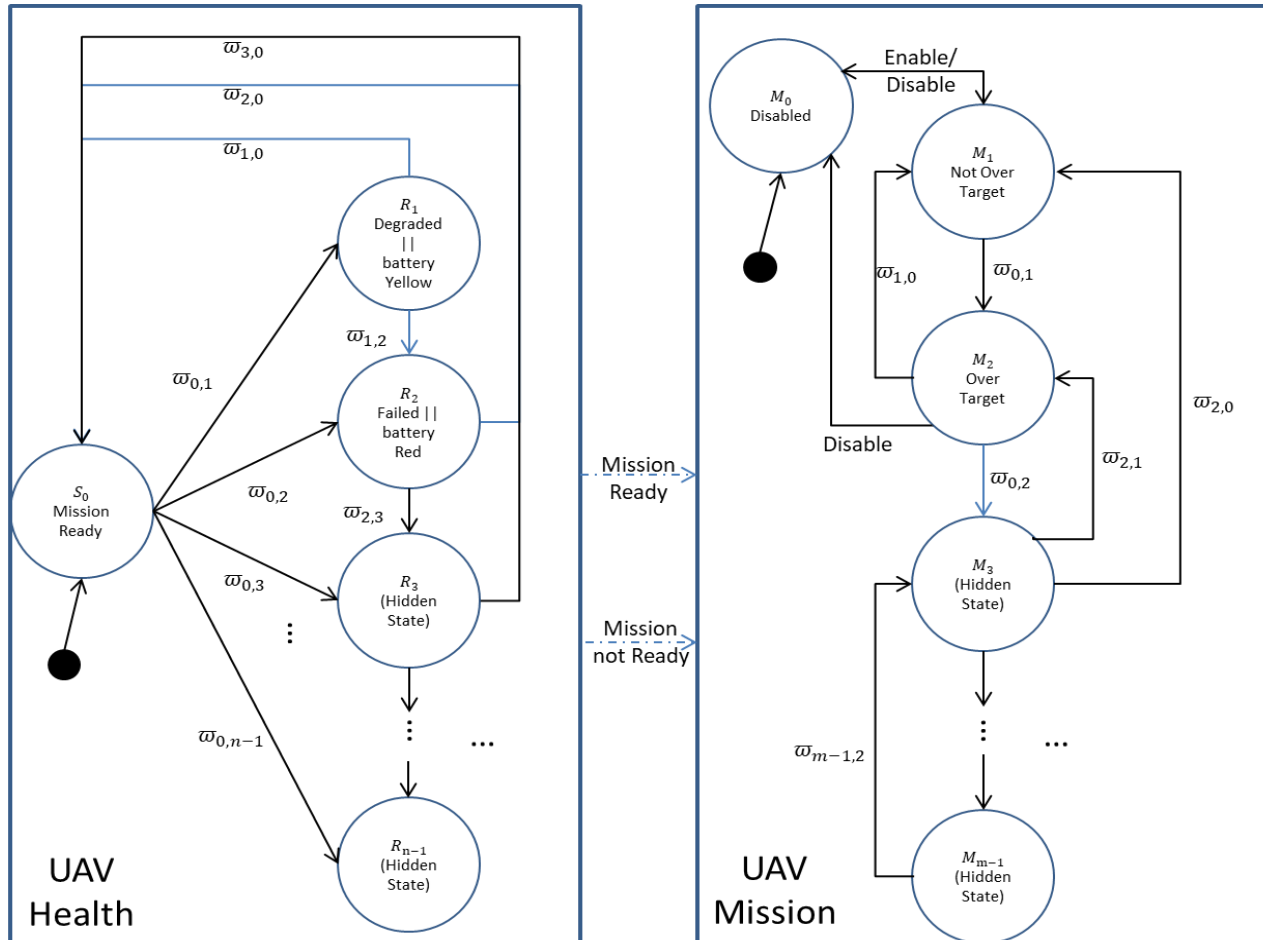

Exemplar Contracts

1. \neg overTarget && healthy && batteryGreen \rightarrow move_to_target
2. \neg batteryRed && degraded || batteryYellow \rightarrow move_to_base
3. batteryRed || failed \rightarrow land
4. unknownHealth || unknownBattery \rightarrow move_to_base
5. overTarget && CTR && healthy \rightarrow takeImages & hover
6. overTarget && NW && healthy \rightarrow takeImages & move SE
7. overTarget && NE && healthy \rightarrow takeImages & move SW
8. overTarget && SW && healthy \rightarrow takeImages & move NE
9. overTarget && SE && healthy \rightarrow takeImages & move NW

Simplified POMDPs: Health and Mission Models

Fitness Function to Maximize Coverage

- Discretize perimeter area into tiles
 - goal: one or two cameras observing each tile (more than two is redundant and should not be rewarded)
 - closer coverage (higher resolution of imaging) is better
- Simple approach: for each tile and each camera
 - if tile is visible from camera, sum up $1/(\text{distance to camera})$
 - cap each tile sum to avoid rewarding redundant coverage
- Future improvements to fitness function
 - reward views from widely separate camera locations to maximize available information e.g. stereo
 - account for different camera capabilities e.g. higher resolution on fixed building cameras

Multi-Level Coverage Algorithm

- Multi-agent control
 - multiple QCs move independently to maximize their contributions to the fitness function
 - resulting cooperative motion works to increase fitness
- Adaptation to changing circumstances
 - for example: one QC crashes or runs low on battery
 - other QCs move to adapt to the changed coverage
- Human-in-the-loop
 - if multi-agent control is insufficient to provide adequate coverage, human intervention is requested
 - at this point it is up to the human to act, e.g. launch additional QC

Multi-UAV Dashboard Prototype

■ Purpose

- customizable dashboard for monitoring and control of multiple simulated and physical vehicles

■ Underlying technologies

- dronekit platform with visualization facilities
- quadcopters (hardware) and quadcopter simulation models
- quadcopter planning and decision-making model
- quadcopter controller

■ Key capabilities

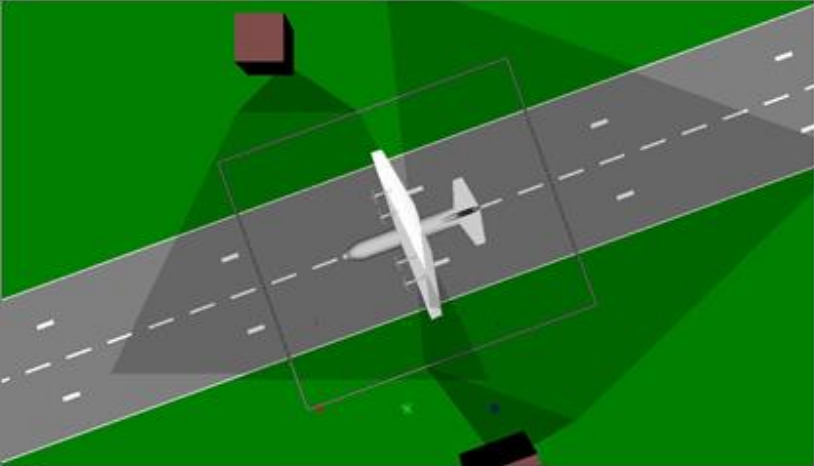

- simulated vehicles exhibit behavior of physical vehicle
- same commands used to control vehicle models and the physical vehicles (quadcopters)
- can switch from simulated to physical vehicles, and vice versa

--	---	--

Human Behavior Modeling

- An important aspect of gauging performance of CPHS in nominal and contingency scenarios (use cases)
 - effects of cognitive load, fatigue, and attention level on error rates
- Key research questions:
 - What aspects of humans to represent in specific problem contexts?
 - Is there a methodological basis to determine an appropriate sparse representation of a human?
 - At what level should human (model) be incorporated in CPHS feedback loop (e.g., on-the-loop, in-the-loop, inside controller, inside system model)?
 - What combination of modeling approaches (e.g., math model, parametric model, probabilistic model, optimal control model) to use for a specific CPHS?

Machine Learning

- Determine unidentified system states during system operation / use
- Determine unidentified environment states during mission execution
- Capture human priorities and preferences in different contexts in simulated operational environments

Machine Learning: Opportunities and Complicating Factors

- Sources of learning
 - sensors
 - networks
 - people
- Complicating factors
 - partial observability
 - noisy sensors
 - disruptive events
 - hostile/deceptive actors in environment

Machine Learning Methods

■ Supervised Learning

- requires labeled data
- creates a data model with offline training
- **application:** learn human's information seeking policies in different contexts

■ Unsupervised Learning

- creates data clusters
- learns patterns and behaviors
- continue learning/ training/ refining model online during execution
- **application:** learn intrusion patterns in aircraft perimeter security

■ Reinforcement Learning

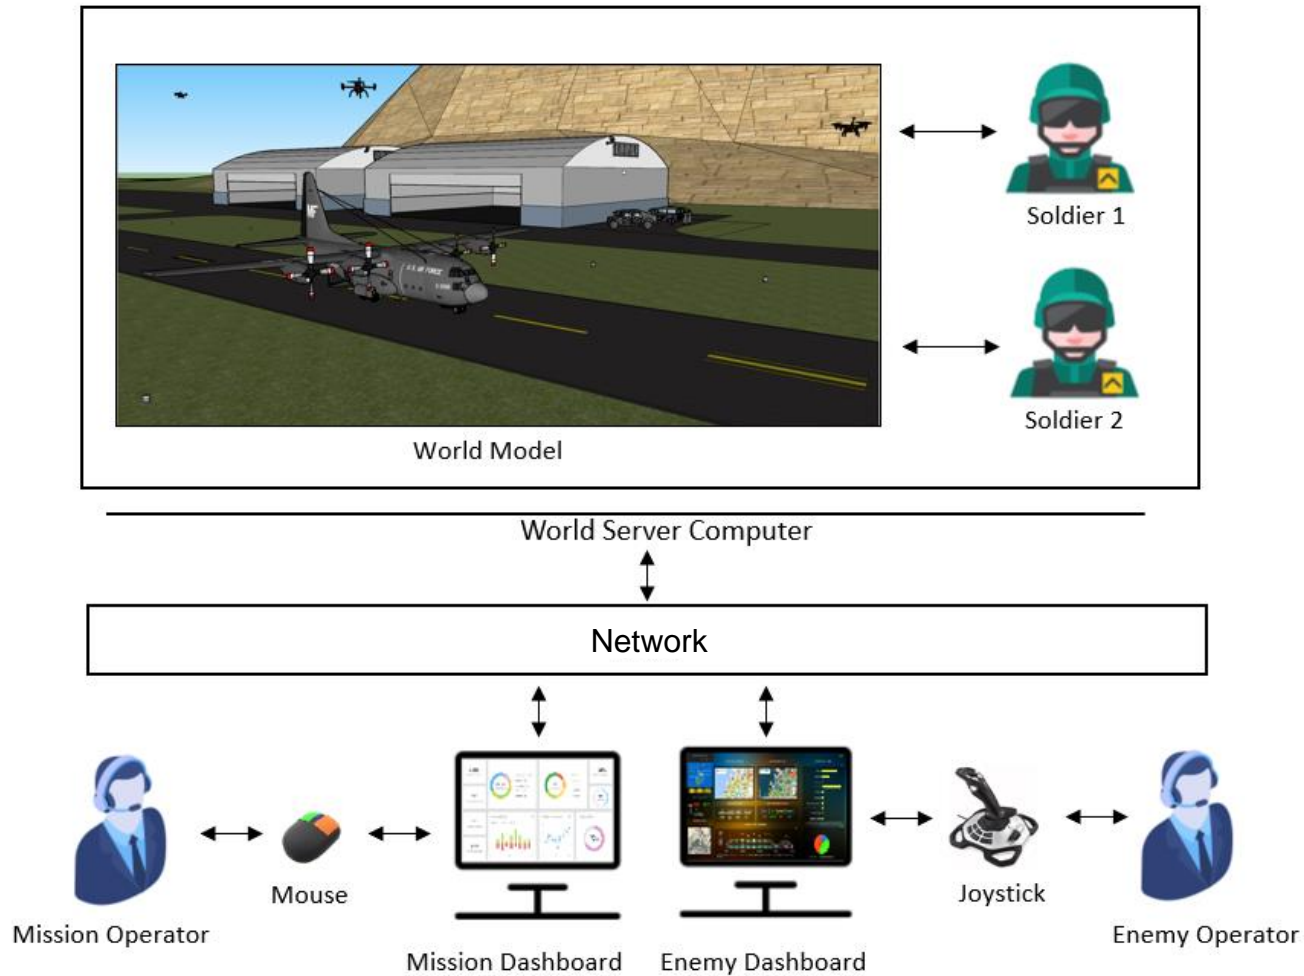

- requires real-time interaction with environment (observation)
- makes decisions (action) based on the existing patterns (states) and real-time environmental feedback (observation)
- **application:** progressively learn system and environmental state based on incoming sensor reports in partially observable environments

Prototype Testbed Hardware

Implementation: Distributed Simulation Architecture

Findings To-Date

- Key problem in implementing hybrid models
 - resolving mismatch between planning & and vehicle control layer

- Mismatch resolution
 - ensure that propagated commands from planning layer to controller do not violate physical and regulatory constraints
 - propagate execution constraints from control layer to PDM layer before planning and decision-making function issues commands
 - incorporate heuristics (e.g., priorities, region of influence) to resolve conflicts and simplify computation

- Adaptive model selection
 - key heuristic: use simplest model that fits system function and environment characteristics
 - e.g., navigate to designated area with partial observability, maintain flight pattern to assure target area coverage

Findings To-Date (cont'd)

- POMDP and vehicle controller work on different time scales
 - dynamics model runs every 0.01 seconds (accuracy)
 - POMDP runs slower (high level decisions/commands)
 - waypoint navigation with goal of minimizing response time to action
 - ideal sampling period for POMDP determined experimentally
- Simultaneous creation of prototype and testbed - good strategy
 - introduced rigor in experimentation
 - current: able to switch between simulation model and physical system
 - future: incorporate operational data from physical system into simulation model to create Digital Twin
- Monitoring and execution dashboard – a key capability
 - facilitated understanding and debugging of vehicle behaviors

Next Steps

- Collaborate with David Jacques of AFIT to integrate our respective technologies
 - probabilistic system modeling
 - UAV test environments
- Expand Modeling and Simulation testbed capabilities
 - more extensive data collection
 - digital twin modeling
 - distribute computation for sensors and adversary behaviors

Takeaways

- DoD systems in 21st century need to be resilient to operate safely in uncertain, partially observable, potentially hostile environments
- Adaptive CPHS, an example of a 21st century system, poses unique modeling, analysis and distributed autonomy challenges
- System model verifiability (safety), flexibility (resilience), and machine learning (adaptation) are essential requirements
- Resilience Contract, a probabilistic model-based construct, satisfies these requirements
- Modeling today is a closed loop process spanning both build-time and run-time environments
- Model adaptation implies not only changes in model parameters but also modeling construct (“principle of proportional complexity”)
- Extensible distributed simulation used to implement adaptive CPHS with distributed autonomy
- Approach successfully applied to perimeter security of military aircraft
